

Topology and Gauge Geometry Underlying the Mesh Programme

A Unified Mathematical Framework for Connections, Curvature, Linking, Defects, and Conserved
Topological Charges

Mark Palmer · with computational collaboration by Claude (Anthropic)

Charlotte, NC · palmer100@gmail.com

Naming note (5 September 2026). This programme is now the Mesh Programme and the theory it develops the mesh framework; 'the rope framework' in earlier revisions reads 'the mesh framework'. 'Rope' remains the name of the two-strand wound object, and the Rope Hypothesis credited to Bill Gaede keeps its name. Identifiers (repository, rope_solver, file names, claim IDs) are unchanged.

Abstract

Ontology versus description (GG-005, GG-006). The claim that the ropes physically instantiate the gauge bundle — that the topological structure IS charge rather than merely describing it — is an ontological hypothesis, not a theorem (GG-005, Conjecture). It is clarifying to state what a weaker, checkable version establishes. Gaede's original ontology takes charge to be a geometric handedness of the two strands (electron and positron as mirror images), with no separate charge entity. A handedness computed directly from strand curves is integer-valued, exactly mirror-antisymmetric, and conserved under smooth deformation — the same integer as the linking number (GG-006, Derived; benchmarks/em/strand_handedness.py). Hence the topological invariants of this paper are best read as the continuum LANGUAGE for Gaede's conserved strand geometry: the geometry is what physically exists, the topology is how it is described after coarse-graining. GG-005 remains the open question of whether that description is, at bottom, an identity.

Across the classical corpus the same mathematical objects recur — fibre bundles, connections, curvature, winding numbers, linking numbers, the Hopf invariant, Chern numbers, homotopy groups — derived apparently independently in the mechanics, electromagnetism, electricity, defect, and soliton papers. This paper is not new physics; it is the mathematical Rosetta Stone that shows those objects are different projections of ONE geometric structure. We build the structure from the ground up: the rope orientation is a section of a fibre bundle over spacetime; comparing orientations at different points requires a connection A ; the failure of an orientation to return unchanged around a loop is the curvature $F = dA$; and the conserved integers of the theory — winding, linking, Hopf, Chern — are the topological invariants of that bundle. The unification is not merely asserted: its keystone, that the Hopf invariant equals the linking number of two preimage fibres, is computed with the SAME linking routine the charge and defect sectors use, so charge-linking and the Hopf invariant are literally one computation on different objects (benchmark benchmarks/topology/gauge_geometry.py, 5/5). We locate every major paper on a single dependency map, give a glossary and a rope-to-standard-mathematics dictionary, and — crucially — keep the mathematics strictly separate from the ontology: the mathematics establishes the bundle, connection, curvature, and topology; the rope hypothesis additionally PROPOSES that physical strands instantiate them. Those are different statements, and the paper marks the line between them throughout.

What this paper is, and is not

IS: a unified mathematical framework showing that the corpus's recurring objects (bundle, connection A , curvature $F=dA$, winding, linking, Hopf, Chern, homotopy) are one geometric structure; the keystone Hopf = linking-of-preimages is computed.

IS NOT: new physics, and NOT a claim that the mathematics proves the rope ontology. The mathematics is standard and stands alone; the ontology (that ropes physically instantiate these objects) is a separate proposal, marked as such in Part IX.

Part I — Mathematical Primitives

1.1 The rope state space

Before any physics, fix the mathematical object. At each point of space the rope medium has an internal state — an orientation, a phase, a handedness, a local frame. The set of possible internal states is the ORDER-PARAMETER SPACE, and which space it is determines everything topological that follows:

- A single angle (phase, planar orientation) lives on the circle S^1 . This is the setting of the defect and thermodynamics papers.
- A direction in space (an axis without a phase) lives on the sphere S^2 . This is the target of the Hopf map in the soliton sector.
- A full rotation/frame lives on $SU(2) \cong S^3$ (or $SO(3)$). This is the setting where linking and the Hopf fibration appear.

The topology of the order-parameter space is WHY topology appears in the physics at all: the conserved integers are properties of maps into S^1 , S^2 , or S^3 , not of the rope dynamics per se. This single observation already unifies a great deal — winding, Hopf, and defect classification are all statements about these spaces.

1.2 Fibre bundles

The orientation is not a single global value; it is a value AT EACH POINT of spacetime. The mathematical object for 'a space of internal states attached to every point of a base space' is a FIBRE BUNDLE:

$$\text{Fibre } F \rightarrow \text{Total space } E \rightarrow \text{Base space } M, \quad (1.1)$$

where the base M is spacetime, the fibre F is the order-parameter space (S^1 , S^2 , or $SU(2)$), and a choice of orientation everywhere is a SECTION of the bundle. We build the abstraction in this generality first, deliberately not yet specialising to the Hopf bundle: the Hopf fibration is one important bundle, but connections, curvature, and topological invariants are features of bundles in general, and seeing them generally is what reveals why they recur.

Part II — Connections

This is the pivot of the whole framework. An orientation at one point and an orientation at another cannot be compared directly — they live in different fibres, different copies of the order-parameter space. To compare them, to differentiate the orientation field at all, one needs a rule for transporting a state from one fibre to a neighbouring one. That rule is a CONNECTION.

connection A : a rule for parallel transport between neighbouring fibres (2.1)

Without a connection, the phrase ‘the phase here versus the phase there’ is meaningless, because there is no canonical identification of one fibre with the next. The logical chain is stark:

No connection $\rightarrow$ no comparison of orientations $\rightarrow$ no derivative of the field $\rightarrow$ no dynamics.

So the connection A is not an optional add-on and it is not, at this stage, electromagnetism. It is the minimal geometric structure required to have a field theory of orientation at all. The rope medium, by having orientations that must be compared across space to define any energy of misalignment, REQUIRES a connection. That the connection later turns out to carry electromagnetism is a result, derived below — not the definition.

Connection — the geometric necessity

A connection A is the rule that makes orientation-comparison, and hence differentiation and dynamics, possible. It is forced by the existence of the orientation field, not added to it. Only in Part III does its curvature turn out to be the electromagnetic field.

Part III — Curvature

Given a connection, transport a state around a small closed loop and ask whether it returns unchanged. In general it does not: the mismatch after a round trip is the CURVATURE,

$$F = dA, \quad (3.1)$$

the exterior derivative of the connection. The universal geometric statement is this: curvature measures the failure of an orientation to return to itself after parallel transport around a closed loop. Nothing in that sentence mentions electromagnetism. It is a statement about bundles.

Where electromagnetism enters. For a rope medium whose order-parameter phase is a $U(1)$ circle, the connection A is a one-form and its curvature $F = dA$ is a two-form with exactly the structure of the electromagnetic field strength — E and B are its components. The homogeneous Maxwell equations $dF = 0$ are then the Bianchi identity (true of any $F = dA$ identically), and the inhomogeneous equations follow from the Chern–Weil relation between curvature and charge in three spatial dimensions. This is the electromagnetism paper’s result, now seen in its place: Maxwell is the curvature theory of the orientation bundle. We identify F with the electromagnetic field only AFTER establishing it as curvature, exactly so the geometric content is not smuggled in through the physics.

Curvature — the universal statement

$F = dA$ measures the holonomy of a small loop: how much an orientation fails to return unchanged. Identifying F with the electromagnetic field is a subsequent step ($U(1)$ phase, $d=3$), not the definition of curvature.

Part III^{1/2} — Why Topology Appears at All

The paper has said topology appears because the order parameter lives on S^1 , S^2 , or S^3 . That is true, but it is not the deepest reason. The deeper reason is a single contrast: local geometry can be continuously deformed; global topology cannot.

Local geometry deforms; a global integer cannot. The connection, the curvature, the precise shape of an orientation field are all local, and all can be smoothly deformed. But an integer cannot change continuously — it cannot drift from 1 to 2 without passing through forbidden non-integer values. Any quantity that is (a) integer-valued and (b) a continuous function of the field is therefore CONSTANT under all smooth deformation. That is the entire source of topological conservation.

This is why the programme's conserved integers are conserved. Winding, linking, Hopf, and Chern are each an integer computed from the field by a continuous formula (a contour, Gauss, or curvature integral). Being integer-valued and continuous in the field, they cannot change under any smooth evolution — conserved not because a dynamical law forbids change, but because CONTINUITY does. A local equation of motion moves the field smoothly, and a smooth motion cannot alter an integer.

integer-valued + continuous in the field $\Rightarrow$ invariant under all
smooth deformation (3.5)

So topology is not introduced into the programme; it is inevitable the moment there are integer-valued continuous functionals of a field. Local equations cannot change global integer invariants — that one sentence explains why winding, linking, Chern, and Hopf are conserved and why they recur in every sector with an orientation field.

Why topology is inevitable

Local geometry deforms continuously; a global integer cannot. Any integer-valued continuous functional of the field is conserved under all smooth dynamics. Winding, linking, Hopf, and Chern are exactly such functionals — their conservation is forced by continuity, not by a dynamical law.

Part III^{3/4} — Why These Structures Are Unavoidable

The same inevitability applies to the machinery itself. Given only four things — an orientation field, continuity, locality, and the need to compare orientations at neighbouring points — each structure is forced, in order:

- Holding an internal orientation at every point IS having a SECTION of a bundle — that is what ‘an internal state at each point’ means. The bundle is the definition of the situation, not a modelling choice.
- COMPARING orientations at neighbouring points — needed for any misalignment energy, derivative, or dynamics — IS having a CONNECTION A. Without it comparison is undefined.
- Asking whether comparison is path-independent — whether transport around a loop returns the orientation unchanged — IS computing the CURVATURE $F = dA$. It is the unavoidable question about any connection.
- Counting how the field wraps, threads, or covers the order-parameter space IS computing its TOPOLOGICAL INVARIANTS, which by Part III½ are automatically conserved.

The conclusion is stronger than ‘here is mathematics that fits.’ Bundles, connections, curvature, and topology are the MINIMUM mathematics capable of describing an orientation field at all. Any theory with a locally-comparable internal orientation — the rope medium included — must contain these structures, because each is forced by the previous demand. The programme did not choose this mathematics for elegance; it is the least mathematics a theory of orientation can have.

The forced chain

orientation field $\rightarrow$ (section of a) BUNDLE; + locality & comparison $\rightarrow$ CONNECTION A; + path-independence question $\rightarrow$ CURVATURE $F=dA$; + integer counts $\rightarrow$ conserved TOPOLOGY. Each step forced by the previous demand — the minimum mathematics for orientation, not a chosen model.

Part IV — Topological Invariants

The conserved integers of the corpus are the topological invariants of the bundle, and they form a hierarchy. Each is computed in the accompanying benchmark; the point of gathering them here is that they are not separate inventions but successive invariants of one structure.

4.1 Winding number — $\pi_1(S^1)$

For a phase field, the winding number counts how many times the phase wraps through 2π around a loop: the class in $\pi_1(S^1) = \mathbb{Z}$. It is the invariant behind phase winding, electric current as transported winding, and the vortex charge of the defect paper. Computed: integer values $+1, -1, +2$ for singly, oppositely, and doubly wound configurations.

4.2 Linking number — the Gauss integral

For two closed loops, the linking number is the signed count of how many times one threads the other, the Gauss double integral (4.1):

$$Lk = (1/4\pi) \oint \oint (\mathbf{r}_1 - \mathbf{r}_2) \cdot (d\mathbf{r}_1 \times d\mathbf{r}_2) / |\mathbf{r}_1 - \mathbf{r}_2|^3 \in \mathbb{Z} . \quad (4.1)$$

It is the invariant behind the electricity paper’s topological charge and the defect paper’s loop linking. Self-linking (writhe) is its single-curve analogue. Computed: $|Lk| = 1$ for a linked pair, 0 for an unlinked pair.

4.3 Hopf invariant — the keystone

The Hopf map $S^3 \rightarrow S^2$ assigns to each point of S^3 a point of S^2 ; the PREIMAGE of a point of S^2 is a circle in S^3 , and the preimages of two distinct points are LINKED circles. The Hopf invariant is the linking number of those two preimage circles:

$$H = \text{Lk}(\text{preimage}(p_1), \text{preimage}(p_2)) . \quad (4.2)$$

This is the keystone of the entire unification, and the benchmark computes it explicitly: constructing two Hopf fibres over distinct points of S^2 and feeding them to the SAME linking routine used for electric charge returns $H = 1$. That is why the Hopf structure kept reappearing in the soliton sector — it is not a separate phenomenon but the linking invariant applied to the fibres of the orientation bundle. Charge-linking and the Hopf invariant are, computationally, one operation on different curves.

4.4 Chern number — integral of curvature

The first Chern number is the integral of the curvature over a closed surface,

$$c_1 = (1/2\pi) \int F \in \mathbb{Z} , \quad (4.3)$$

an integer measuring the total curvature (flux) threading the surface. It is the invariant behind Gauss's law — total charge as quantised flux — and behind flux quantisation generally. Computed as $c_1 = 1$ for a unit-charge configuration. Gauss's law is thus the Chern-number statement for the orientation bundle, tying the electricity and Maxwell papers to the same invariant hierarchy.

The invariant hierarchy — all computed

Winding $\pi_1(S^1)=\mathbb{Z}$ (defects, current); Linking Gauss integral (charge, defect loops); Hopf invariant = linking of preimages (solitons) — KEYSTONE; Chern number = curvature integral (Gauss law, flux). Benchmark 5/5, Hopf and charge-linking shown to be one routine.

Part V — Homotopy: One Classification of All Defects

The defect papers classified topological defects by homotopy group; here that classification is seen as one table, the homotopy groups of the order-parameter space deciding which defects exist in each sector:

Homotopy group	Detects	Rope-sector appearance
π_0	disconnected vacua $\rightarrow$ domain walls	absent for S^1, S^2 (connected)
π_1	loops $\rightarrow$ line defects / vortices	vortex lines, winding, current
π_2	spheres $\rightarrow$ point defects / monopoles	absent for S^1 ($\pi_2(S^1)=0$): no monopoles
π_3	3-sphere maps $\rightarrow$ textures	Hopf textures / solitons (S^2 target)

The defect taxonomy of the 3D-topology paper is exactly this table read for the rope's order-parameter spaces: for the S^1 phase, π_1 gives vortices and $\pi_2 = 0$ forbids monopoles; for the S^2 direction field, π_3 gives the Hopf textures of the soliton sector. One homotopy table, several papers.

Part VI — Gauge Invariance Is Forced, Not Added

A choice of how to label the phase — where $\theta = 0$ sits at each point — is a convention. Physics cannot depend on it. Changing the convention smoothly from point to point is a GAUGE TRANSFORMATION, and it shifts the connection by $A \rightarrow A + d\chi$ while leaving the curvature $F = dA$ unchanged (since $d^2\chi = 0$).

The beautiful statement. Gauge symmetry is not an extra postulate layered onto the theory. It is FORCED: the moment one admits that the phase labelling is a convention, invariance under changing that convention is automatic, and the connection must transform as $A \rightarrow A + d\chi$ for the physics (the curvature) to be convention-independent. Gauge invariance is the statement that nothing physical depends on the arbitrary choice of phase origin — and that the electromagnetic potential's gauge freedom is precisely this arbitrariness. The mesh programme does not add gauge symmetry; it cannot avoid it.

Gauge invariance — forced

Phase labelling is a convention $\rightarrow$ physics is invariant under changing it $\rightarrow A \rightarrow A + d\chi$ with F invariant. Gauge symmetry is a consequence of the bundle description, not an added assumption.

Part VII — Everything in One Diagram

The whole framework, in one picture. Every arrow is a mathematical step established above.

The left branch (homotopy $\rightarrow$ defects $\rightarrow$ linking) and the right branch (bundle $\rightarrow$ connection $\rightarrow$ curvature) are not two subjects. They meet: the Hopf invariant that classifies the right branch's textures IS the linking number that classifies the left branch's loops, and both feed the single pool of conserved integer topology. That meeting point is the keystone computed in the benchmark.

7.1 The reverse direction: from measured integers to hidden geometry

The diagram reads top-down — orientation to bundle to connection to curvature to invariants — but the physically important direction is often the reverse. An experimenter does not see the bundle; they measure conserved INTEGERS — a quantised charge, a quantised flux, a discrete winding — and from those infer the geometry behind them:

measure conserved integers → infer topology → infer a bundle → infer a connection.

This is philosophically powerful and historically accurate: physicists repeatedly discovered topology EXPERIMENTALLY — quantised Hall conductance, flux quantisation, quantised charge — before recognising the fibre-bundle geometry underneath. An integer that refuses to change is the observable signature of a hidden bundle; the geometry is inferred from the quantisation, not the other way round. For the mesh programme this means the framework is not only a way to organise known results top-down, but a claim that can be approached from the bottom up: wherever the medium exhibits a robust conserved integer, the bundle–connection–curvature structure is implied, and the specific invariant (winding, linking, Chern) identifies which topological feature is responsible.

Part VII½ — One Organizing Principle

The framework supports one strong organizing statement, which the paper can now make explicitly:

Organizing principle
Every conserved quantity in the classical mesh programme is, ultimately, an INTEGER arising from topology.

The four principal conserved quantities of the corpus are each a topological integer:

Conserved quantity	Topological integer
Electric charge	Chern number $\int F$ / linking number
Electric current	transported winding number
Soliton / knot content	Hopf invariant (= linking of preimages)
Defect content	homotopy class (winding of π_1)

So the conserved integers are not separate conservation laws with separate origins — they are one phenomenon (an integer-valued continuous functional cannot change, Part III½) seen through four topological invariants. Conservation of charge, current, soliton number, and defect number are four faces of the same fact — the organizing principle the corpus had used implicitly, now stated outright.

Part VIII — Dependency Map: Where Every Paper Sits

The payoff for the reader: each major paper is located by the mathematical object it develops.

Mathematical object	Where it is developed
Fibre bundle, order parameter	Foundations / microscopic mechanics
Coarse-graining to a field	Homogenization
Connection A	Electromagnetism
Curvature $F = dA$	Maxwell equations
Winding number π_1	Defect theory
Linking number (Gauss)	Electricity / charge
Hopf invariant (= linking of preimages)	Solitons; unified here
Chern number ($\int F$)	Charge / Gauss law
Homotopy classification	3D defect topology
Equilibrium statistics of the field	Statistical mechanics

Read top to bottom, this is the corpus's mathematical spine: a bundle with a connection, its curvature, and the tower of topological invariants — with each physics paper developing one level. The machine-readable dependency graph ([docs/dependency_graph.txt](#)) encodes the same relationships claim by claim.

Part IX — What Is NOT Claimed: Mathematics vs Ontology

This is the most important boundary in the paper, and keeping it sharp is what makes the framework credible. There are two entirely different kinds of statement here, and they must not be conflated.

The mathematics ESTABLISHES	The ontology additionally PROPOSES
a fibre bundle over spacetime	that physical rope strands instantiate the bundle
a connection A on it	that a physical medium realises parallel transport
curvature $F = dA$	that F is a physical electromagnetic field
integer topological invariants	that these are physical conserved charges
gauge invariance of F	that gauge freedom is physical convention

The line, stated plainly. The left column is standard mathematics: bundles, connections, curvature, and topological invariants exist and have these properties independent of any physical hypothesis, and this paper merely assembles them. The right column is the rope hypothesis: the ADDITIONAL, physical claim that the rope medium instantiates these objects — that there really are strands whose orientation is the bundle section, whose comparison is the connection, whose loop holonomy is the electromagnetic field. The mathematics does not prove the ontology; a consistent geometric framework is necessary for the ontology but not sufficient to establish it. Every physical identification in this paper (F is electromagnetism, linking is charge, winding is

current) belongs to the right column and is flagged as a proposal, not a theorem. The mathematics is offered as rigorous; the ontology is offered as the hypothesis under test.

The separation, once more

PROVEN (mathematics): bundle, connection, curvature, winding/linking/Hopf/Chern, gauge invariance — standard, assembled and computed here.

PROPOSED (ontology): that physical ropes instantiate these objects, so that curvature is the EM field and topology is physical charge. Necessary-but-not-sufficient; this is the hypothesis, not a consequence of the mathematics.

Appendix A — Glossary

Term	Meaning
Fibre	the space of internal states attached to one point of spacetime
Section	a choice of internal state at every point (an orientation field)
Connection	a rule for transporting internal states between neighbouring points
Holonomy	the net change after transport around a closed loop
Curvature	$F = dA$; the holonomy of an infinitesimal loop
Winding number	π_1 class: times a phase wraps around a loop
Linking number	Gauss integral: times one loop threads another
Hopf invariant	linking number of two preimage fibres of $S^3 \rightarrow S^2$
Chern number	$(1/2\pi)\int F$: quantised total curvature through a surface
Homotopy group π_n	classes of maps from S^n into the order-parameter space

Appendix B — Rope-to-Mathematics Dictionary

The single most useful translation table: it lets a mathematician and a physicist read the same corpus in their own language.

Standard mathematics	Rope interpretation
Fibre bundle	orientation attached to every point of spacetime
Principal bundle	the orientation bundle (U(1)/SU(2) structure)
Fibre	local internal state (orientation/phase)
Section	physical orientation field
Base space	spacetime

Structure group	the symmetry of the internal state (U(1), SU(2))
Order parameter	the internal orientation variable
Connection A	rule comparing neighbouring rope orientations
Gauge field	the connection A
Covariant derivative	orientation comparison across points
Parallel transport	carrying an orientation along a path
Holonomy	accumulated orientation mismatch around a loop
Wilson loop	measurable holonomy of a closed loop
Curvature $F = dA$	failure of orientation to return around a loop
Field strength	the curvature F (its E, B components)
Flux	integrated curvature through a surface
Berry phase	accumulated bundle phase under transport
Gauge transformation	change of phase convention $A \rightarrow A + d\chi$
Gauge orbit	set of equivalent phase conventions
Gauge invariance	independence from the phase-origin choice
Winding number π_1	times the phase wraps around a loop
Linking number	times one loop threads another (Gauss integral)
Self-linking / writhe	a curve's linking with its own framing
Hopf invariant	linking number of two preimage fibres ($S^3 \rightarrow S^2$)
Chern number	quantised total curvature $(1/2\pi)\int F$
Homotopy group π_n	classes of maps $S^n \rightarrow$ order-parameter space
Electric charge	Chern number / linking number
Electric current	transport of winding number
Defect	homotopy singularity of the order parameter
Vortex / vortex line	π_1 line defect
Knotted soliton	Hopf map of nonzero Hopf invariant

Status of Each Result

Result	Status
Order parameter $\rightarrow$ topology ($S^1, S^2, SU(2)$)	Derived — standard; assembled
Bundle / connection / curvature framework	Derived — standard differential geometry
Winding, linking, Chern invariants	Derived — computed integers
Hopf invariant = linking of preimages	Derived — KEYSTONE, computed (same routine as charge)

Homotopy classification of defects	Derived — unifies the defect papers
Gauge invariance is forced	Derived — convention-independence of F
F is the electromagnetic field	Proposed (ontology) — identification, not theorem
Ropes physically instantiate the bundle	Proposed (ontology) — the hypothesis under test

Conclusion

The mathematics scattered across the classical corpus is one structure. A rope orientation is a section of a fibre bundle; comparing orientations requires a connection A ; the failure of an orientation to return around a loop is the curvature $F = dA$; and the conserved integers — winding, linking, Hopf, Chern — are the topological invariants of that bundle, forming a single hierarchy. The unification is demonstrated, not merely asserted: its keystone, that the Hopf invariant is the linking number of two preimage fibres, is computed with the same routine that computes electric charge, so the objects that appeared independently across the soliton, charge, and defect papers are shown to be one computation on different curves. Homotopy classifies all the defects in one table; gauge invariance is forced by the arbitrariness of the phase convention rather than added; and a single diagram and dependency map locate every paper on the shared geometric spine, and Part IX draws the one line that matters: the geometry is standard mathematics, while the claim that ropes instantiate it is the hypothesis under test. What this paper adds is not a new result but a change in how the corpus reads: the reader finishes seeing that the recurring objects were never separate derivations, but different projections of one underlying geometry — which is what a mathematical reference for the rest of the classical corpus should provide.

Registered Claims in This Paper

Each statement below is traceable to the machine-readable registry (claims.yaml), the corpus's single source of truth. Status labels: Derived (follows from stated mechanics), Modeled (reproduces data with declared inputs), EFT-constrained (bounded by effective-theory limits), Conjecture (proposed, not derived), Open (registered unsolved problem), Failed (falsified, kept as a finding). Where a claim is code-backed, the named benchmark reruns it.
